Reconnection is as ubiquitous as plasmas themselves

- Magnetically confined laboratory plasmas
- Laser-solid interactions (inertial confinement fusion)
- Flares (stars, accretion disks, magnetars, blazars)
- Dissipation in magnetized turbulence (solar wind, ISM)
- Turbulent dynamo (magnetogenesis)
- Space weather
- Etc.

Impact

"The prevalence of this research topic is a symptom not of repetition or redundancy in plasma science but of the underlying unity of the intellectual endeavor. As a physical process, magnetic reconnection plays a role in magnetic fusion, space and astrophysical plasmas, and in laboratory experiments. That is, investigations in these different contexts have converged on this common scientific question. If this multipronged attack continues, progress in this area will have a dramatic and broad impact on plasma science."

(S. C. Cowley & J. Peoples, Jr., "Plasma Science: advancing knowledge in the national interest", National Academy of Sciences Decadal Survey on Plasma Physics, 2010)

Reconnection: the key questions

1. Reconnection rate

- Fast, independent of microphysics (?): why?

2. Reconnection trigger

- The reconnection stage proper (explosive) is often preceded by a long, quiescent period: *two timescales*.

3. Energy partition and particle acceleration

- Magnetic energy is converted / dissipated: *how much energy goes into the different channels*?

Reconnection: the key questions

1. Reconnection rate

- Fast, independent of microphysics (?): why?

2. Reconnection trigger

- The reconnection stage proper (explosive) is often preceded by a long, quiescent period: *two timescales*.

3. Energy partition and particle acceleration

- Magnetic energy is converted / dissipated: *how much energy goes into the different channels*?

Despite ~ 60 years of active research, we still don't have a model that accounts for these different aspects in even the simplest plasma description (MHD).

Challenge

- Intrinsic **multiscale / multiphysics** character renders analytical understanding and numerical modeling of magnetic reconnection extremely challenging.
- Inherently **non-steady-state**, so statistical description probably required.
- Wide variety and complexity of physical environments where reconnection occurs: collisional (MHD) *vs.* collisionless (kinetic) plasmas, turbulent *vs.* laminar backgrounds, weakly *vs.* strongly magnetised, etc.

MHD equations

• No intrinsic spatial or temporal scales: all kinetic physics has disappeared. Valid when collisions dominate.

• Very useful set of equations: very often yield key physical insight, even if not rigorously valid for the particular plasma under consideration.

MHD equations

Assuming incompressibility, the linear dispersion relation is

$$\omega = \mathbf{k} \cdot \mathbf{v}_A, \quad \mathbf{v}_A = \frac{\mathbf{B}}{\sqrt{4\pi\rho}}$$

i.e., Alfvén waves.

Frozen flux constraint

Magnetic flux through a surface S, defined by a closed contour C:

В

$$\Psi = \int_S \mathbf{B} \cdot d\mathbf{S}$$

How does Ψ change in time?1. the magnetic field itself can change:

$$\left(\frac{\partial \Psi}{\partial t}\right)_1 = \int_S \frac{\partial \mathbf{B}}{\partial t} \cdot d\mathbf{S} = -c \int_S \nabla \times \mathbf{E} \cdot d\mathbf{S}$$

$$C(\mathsf{t+dt})$$
2. the surface moves with velocity **w**:

$$\left(\frac{\partial \Psi}{\partial t}\right)_2 = \int_C \mathbf{B} \cdot \mathbf{w} \times d\mathbf{l} = \int_C \mathbf{B} \times \mathbf{w} \cdot d\mathbf{l} = \int_C \nabla \times (\mathbf{B} \times \mathbf{w}) \cdot d\mathbf{S}$$

Combine the two contributions to get:

$$\frac{d\Psi}{dt} = -\int_{S} \nabla \times (c\mathbf{E} + \mathbf{w} \times \mathbf{B}) \cdot d\mathbf{S}$$

Up to here, no plasma physics involved – this is a completely general result

Combine the two contributions to get:

$$\frac{d\Psi}{dt} = -\int_{S} \nabla \times (c \mathbf{E} + \mathbf{w} \times \mathbf{B}) \cdot d\mathbf{S}$$

Recognize that \mathbf{w} is an arbitrary velocity. Let me chose it to be the plasma velocity: $\mathbf{w} = \mathbf{u}$, and recall Ohm's law:

$$\mathbf{E} + \frac{1}{c}\mathbf{u} \times \mathbf{B} = \eta_s^2$$

Combine the two contributions to get:

$$\frac{d\Psi}{dt} = -\int_{S} \nabla \times (c \mathbf{E} + \mathbf{w} \times \mathbf{B}) \cdot d\mathbf{S}$$

Recognize that \mathbf{w} is an arbitrary velocity. Let me chose it to be the plasma velocity: $\mathbf{w} = \mathbf{u}$, and recall Ohm's law:

$$\mathbf{E} + rac{1}{c}\mathbf{u} imes \mathbf{B} = \eta \mathbf{j}$$

Neglect collisions (RHS) \rightarrow *ideal Ohm's law*

$$\frac{d\Psi}{dt} = 0$$

Combine the two contributions to get:

$$\frac{d\Psi}{dt} = -\int_{S} \nabla \times (c\mathbf{E} + \mathbf{w} \times \mathbf{B}) \cdot d\mathbf{S}$$

Recognize that \mathbf{w} is an arbitrary velocity. Let me chose it to be the plasma velocity: $\mathbf{w} = \mathbf{u}$, and recall Ohm's law:

$$\mathbf{E} + \frac{1}{c}\mathbf{u} \times \mathbf{B} = \eta \mathbf{j}$$

Hannes Alfvén

Neglect collisions (RHS) \rightarrow *ideal Ohm's law*

Magnetic flux through the arbitrary contour C is constant: **magnetic field lines must move with** (are *frozen* to) **the plasma**

Frozen flux vs. reconnection

Reconnection implies breaking the frozen flux constraint, i.e., going beyond the ideal Ohm's law.

$$\mathbf{E} + \frac{1}{c}\mathbf{u} \times \mathbf{B} = \eta \mathbf{j}$$

But the plasma is a very good conductor, right?

Frozen flux vs. reconnection

Reconnection implies breaking the frozen flux constraint, i.e., going beyond the ideal Ohm's law.

$$\mathbf{E} + \frac{1}{c}\mathbf{u} \times \mathbf{B} = \eta \mathbf{j}$$

But the plasma is a very good conductor, right?

Right. The RHS becomes important *not* because collisions are large, but because sharp gradients of the magnetic field give rise to a large current (hence the term *current layer*).

P. Sweet

$$S = L_{CS} V_A / \eta$$

$$\delta_{SP} / L_{CS} \sim S^{-1/2}$$

$$u_{in} / V_A \sim S^{-1/2}$$

$$cE \sim B_0 V_A S^{-1/2}$$

Sweet ('58) and Parker ('57) attempted to describe reconnection within the framework of resistive magnetohydrodynamics (MHD).

Typical solar corona parameters yield $S \sim 10^{14}$; this theory then predicts that flares should **last ~2 months**; in fact, flares last **15min – 1h**. [still, Sweet-Parker (SP) theory was a great improvement on simple resistive diffusion of magnetic fields, which would yield ~3.10⁶ years...]

The problem

- Most applications of interest have *S*>>1. SP reconnection rates orders of magnitude too slow to explain observations. This was immediately appreciated but how to fix it?
- Most notorious attempt to solve the problem within MHD theory was proposed by Petschek ('63) no convincing evidence for it was ever found.
- Perhaps a more sophisticated description of the plasma is required: kinetic effects?
- It is now widely believed that kinetic reconnection is fast.
- However, many astrophysical environments (e.g. *solar chromosphere, interstellar medium, inside stars and accretion disks*) are sufficiently collisional for MHD to apply, and fast reconnection is expected there.

Is the Sweet-Parker model right?

It seemed so! For a long time, numerical simulations systematically confirmed the SP model, as did dedicated experiments.

Is the Sweet-Parker model right?

It seemed so! For a long time, numerical simulations systematically confirmed the SP model, as did dedicated experiments.

Loureiro and Uzdensky, PPCF 58, 014021 (2016) (Review)

1- Obtain analytical form for a SP-like current sheet (nonlinear steady state solution); this describes the background equilibrium.

1- Obtain analytical form for a SP-like current sheet (nonlinear steady state solution); this describes the background equilibrium.

2- Analyze its linear stability using standard tearing-mode instability techniques. Obtain:

$$\gamma_{\rm max} L_{CS} / V_A \sim S^{1/4}$$
$$k_{\rm max} L_{CS} \sim S^{3/8}$$
Current sheet instability: Threshold

Three conditions required for instability:

$$\gamma_{\max} L_{CS}/V_A \gg 1; \quad k_{\max} L_{CS} \gg 1; \quad \delta_{in}/\delta_{SP} \ll 1$$

Most stringent condition is that on δ_{in} since it bears the weakest dependence on S:

$$\delta_{in}/\delta_{SP} \sim S^{-1/8}$$

Requiring (non-rigorously!) that this be at most 1/3 yields

→ Critical threshold for instability:

(somewhat similar to the transition to turbulence as the Reynolds number increases in hydrodynamics)

Numerical confirmation of linear theory

Direct numerical simulations confirm scalings predicted by linear theory.

Samtaney, Loureiro et al., PRL '09

NONLINEAR THEORY OF STOCHASTIC PLASMOID CHAINS

Nonlinear stage: hierarchical plasmoid chains

Long current sheets ($S > S_c \sim 10^4$) are violently unstable to multiple plasmoid formation.

• Current layers between any two plasmoids are themselves unstable to the same instability if

$$S_n = L_n V_A / \eta > S_c$$

(Shibata & Tanuma '01)

Nonlinear stage: hierarchical plasmoid chains

Long current sheets ($S > S_c \sim 10^4$) are violently unstable to multiple plasmoid formation.

1

• Current layers between any two plasmoids are themselves unstable to the same instability if

$$S_n = L_n V_A / \eta > S_c$$

• Plasmoid hierarchy ends at *the critical layer*:

$$L_{c} = S_{c} \eta / V_{A} ; \ \delta_{c} = L_{c} S_{c}^{-1/2}$$
$$c E_{c} = B_{0} V_{A} S_{c}^{-1/2}$$

(Shibata & Tanuma '01)

Nonlinear stage: hierarchical plasmoid chains

Long current sheets ($S > S_c \sim 10^4$) are violently unstable to multiple plasmoid formation.

(Shibata & Tanuma '01)

• Current layers between any two plasmoids are themselves unstable to the same instability if

$$S_n = L_n V_A / \eta > S_c$$

• Plasmoid hierarchy ends at *the critical layer*:

$$L_{c} = S_{c} \eta / V_{A} ; \ \delta_{c} = L_{c} S_{c}^{-1/2}$$
$$c E_{c} = B_{0} V_{A} S_{c}^{-1/2}$$

• $N \sim L / L_c$ plasmoids separated by near-critical current sheets.

Reconnection in stochastic plasmoid chains

We proposed a statistical model to describe reconnection in stochastic plasmoid chains (Uzdensky *et al.*, PRL '10).

Key results:

- Nonlinear statistical steady state exists; *effective reconnection rate* is:
 E_{eff} ~ S_c^{-1/2} ~ 0.01 → fast, independent of S!
- **Plasmoid flux and size distribution functions** are:

$$f(\psi) \sim \psi^{-2}$$
 ; $f(w_x) \sim w_x^{-2}$

Monster plasmoids form occasionally:
 w_{max} ~ 0.1L → can disrupt the chain, observable.

High-Lundquist-number reconnection

Direct numerical simulations of magnetic reconnection at $S>S_c$

Reconnection and dissipation rates

Sweet-Parker model breaks down for $S > 10^4$ as we predicted

PLASMOIDS IN CONTEXT

Plasmoids in solar flares

Karlicky & Kliem '10

There seems to be abundant evidence for plasmoids in solar flares (and in the Earth's magnetotail) – see Lin '05, Loureiro '13 and refs. therein).

Takasao et al. '12

Plasmoids in tokamaks

Sawtooth instability: Kadomtsev revisited

Plasmoid instability
leads to a 2/2
perturbation, which
is experimentally
observed (possible
explanation for the
triggering of 3/2
NTMs by sawteeth)

Yu, Günter & Lackner, '14; Gunter et al. '15

Plasmoids in turbulent small-scale dynamo

The current sheets that arise in the nonlinear state break into plasmoids when the Reynolds number is large enough (and moderate Pm).

Schekochihin and Iskakov 2007, unpublished

Relativistic pair-plasma reconnection

These ideas remain qualitatively valid in very different plasmas, e.g. relativistic pair-plasma reconnection:

Plasmoids in the laboratory

(Hare et al., PRL'17)

Plasmoids in the laboratory

(Hare et al., PRL '17)

Plasmoids in the laboratory

Hare, Lebedev, Suttle, Loureiro et al., PRL '17

KINETIC RECONNECTION

Alternatively, even if $\,\delta_{SP} >
ho_i, c/\omega_{pi}\,$, one is almost certain to get:

$$\delta_c < \rho_i, c/\omega_{pi}$$

- MHD is valid at large scales.
- Below c/ω_{pi} , ions and electrons decouple: *plasma is no longer a single fluid*. Electrons remain frozen-in.
- Electrons and field lines decouple below c/ $\omega_{\rm pe}$ or $\rho_{\rm e}$

GEM challenge

What is the minimal plasma description that yields fast reconnection rates?

Except for MHD, the reconnection rate found here is ~**0.1V_AB₀**

Note that the MHD simulation reported here is at S<S_c, so this line is just the SP rate

GEM challenge, Birn et al. '01 (but see Daughton '06)

What is the reconnection rate in collisionless plasmas?

• Is **0.1** a universal constant of nature?

What is the reconnection rate in collisionless plasmas?

• Is **0.1** a universal constant of nature?

What is the reconnection rate in collisionless plasmas?

• Is **0.1** a universal constant of nature?

To the best of my knowledge, the reconnection rate in collisionless plasmas is an open question.

Some open questions

- 3D
- Reconnection onset (the two-timescale problem)
- Energy partition, particle acceleration, dissipation mechanisms
- What is the subgrid model that will reproduce the effect of reconnection on small scales?
- Role of background turbulence?
- Role of reconnection in turbulence?

Summary and Conclusions

- Magnetic reconnection is one of the most (the most?) important basic plasma physics phenomenon.
- Basically, it is an explosive reconfiguration of the magnetic field.
- Leads to energy release (e.g., a solar flare)
- It is quite challenging to understand, and has remained at the cutting edge of plasma research for over 50 years (and probably for the next 50 also!)

Summary and Conclusions

- A lot of progress has been made over the last decade or so: very dynamic and symbiotic collaboration between theory, high-performance computing, experiment and observations
- It is credible that in the next 5 years we will have a fairly complete understanding of reconnection in the simplest plasma description – about time!!

Exciting times ahead!
