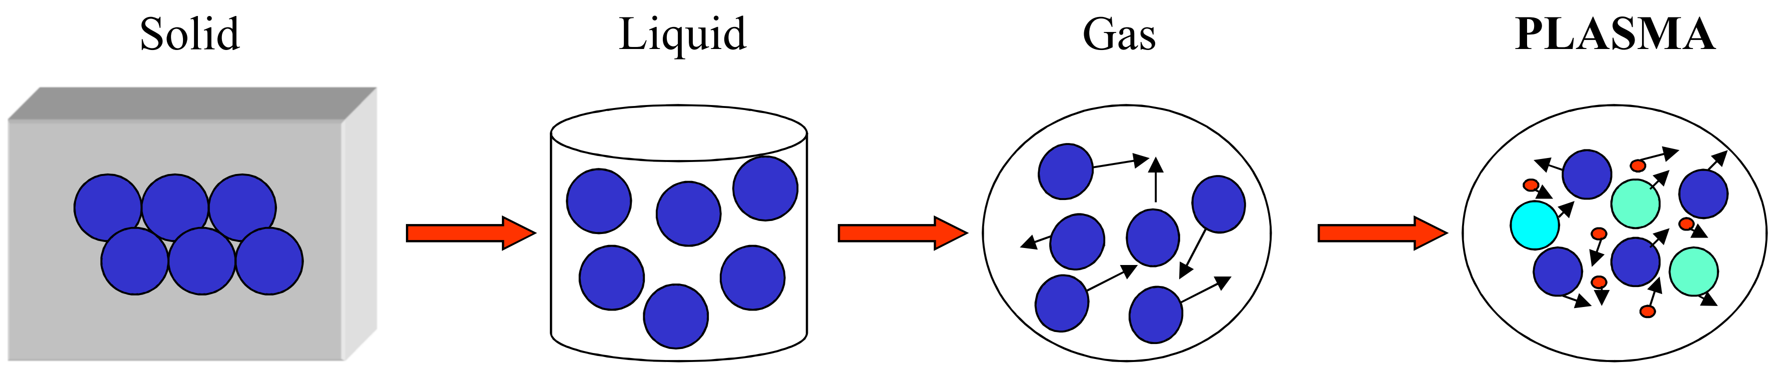
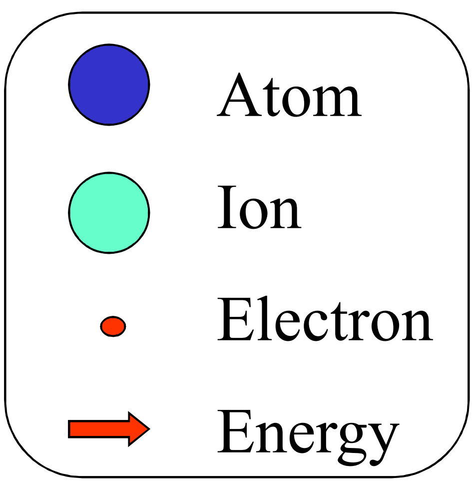
South Orange, New Jersey (USA)

2018 SULI Introductory Course in Plasma Physics

What is a Plasma?

The *Plasma* state is 'The Fourth State of Matter' (99%)





A *Plasma* is a collection of neutrals, ions, and electrons characterized by a *collective behavior*.

S. Eliezer and Y. Eliezer. *The Fourth State of Matter: An Introduction to Plasma Science. Bristol, UK: IOP Publishing (2001)*

Plasma – 1st State of Matter

The U.S. Department of Energy's Princeton Plasma Physics Laboratory (PPPL) is a collaborative national center for plasma and fusion science. Its primary mission is to develop the scientific understanding and the key innovations which will lead to an attractive fusion energy source. Associated missions include conducting world-class research along the broad frontier of plasma science and technology, and providing the highest quality of scientific education.

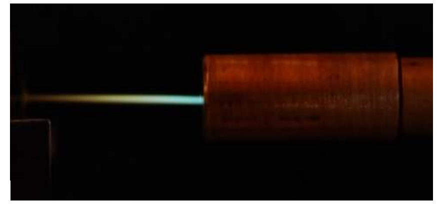
Plasmas 101



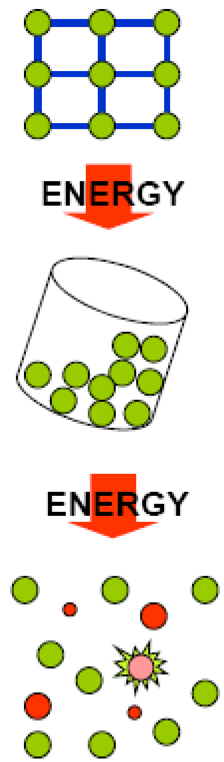
- Molecules
- Excited molecules
- Ions
- Electrons

Solid, Liquid, Gas and …Plasma
-The 4th State of Matter

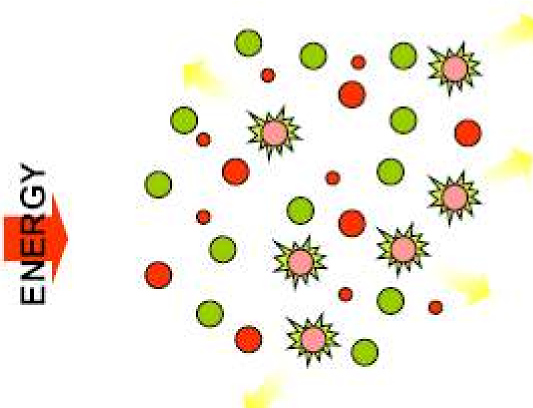
SOLID
- Molecules fixed in lattice
- Electrons bound to molecules or lattice

LIQUID
- Molecule bonds are flexible
- Electrons close to molecules

GAS
- Molecules free to move
- Few electrons and ions that are free to move
- Some excited molecules are present



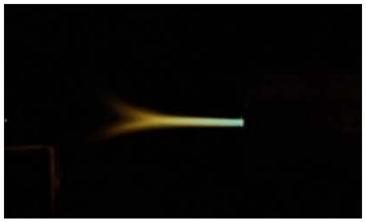
PLASMA
- Molecules free to move
- Many electrons, ions and excited molecules, all free to move
- often accompanied by light



>99% in Universe

SETON HALL UNIVERSITY

The Eventful Plasma World

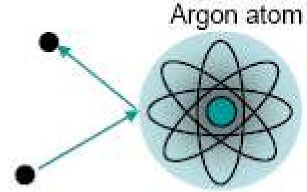


Collisions in a plasma

- Molecules
- Excited molecules
- Ions
- Electrons

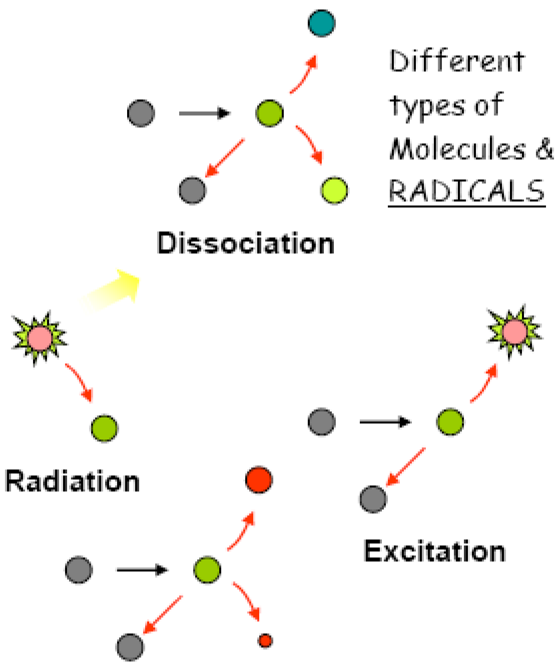
Elastic collisions

Elastic collision are frequent in gases
No energy exchange



essentially no exchange of energy ($m_{Ar} >> m_e$)

Inelastic collisions



Gas

ENERGY

Plasma

Therefore more and stronger collisions leading to more

ionization,
excitation,
dissociation and
radiation

Two Types of plasmas

High-temperature plasmas or Hot (Thermal) plasmas

$T_i \approx T_e \geq 10^7$ K

e.g., fusion plasmas

$T_i \approx T_e \approx T_g \leq 2 \times 10^4$ K

e.g. arc plasma at normal pressure

Low-temperature plasmas or Cold (Non-thermal Plasmas

$T_i \approx T_g \approx 300$ K

$T_i << T_e \leq 10^5$ K

e.g. low-pressure glow discharge

high-pressure cold plasma

Hot vs. Cold Plasmas

Thermal vs. Non-Thermal Plasmas

The plasma components (electrons, ions, neutrals) are characterized by energy distribution functions or alternatively by an "average" energy or temperature (T_e, T_i, T_n) – not quite correct, only true for Maxwell-Boltzmann distributions !!!

Electrons in general have more complicated energy distributions !!!

<u>Thermal Plasma:</u> $T_e \approx T_i \approx T_n$ (a few thousand Kelvin for e.g. torches to $>10^6$ Kelvin for e.g. fusion plasmas)

<u>Non-Thermal Plasma:</u> $T_e >> T_i, T_n$ with $T_i \approx T_n$

- high electron temperature (10,000 – 50,000 K)
- low gas temperatures (300 – 1,500 K)
- "high-temperature chemistry" at low ambient temperatures

(through dissociation and ionization & vibrational non-equilibrium)

Low-Temperature ("Cold") Plasmas [Non-equilibrium, Non-Thermal]

$T_e >> T_i, T_n$ with $T_i \approx T_n$

- High "electron temperature" (10,000 – 100,000 K)
  - T_e from 0.5 eV to 10 eV
  - Often highly non-Maxwellian EEDF; "bulk" and "beam" electrons
- Low gas temperature (350 – 2,500 K)
- "High-temperature chemistry" at low ambient temperatures
  - Electron-driven ionization and dissociation (in molecular plasmas) create reactive radicals
  - Electron interactions (in molecular plasmas) create a vibrational non-equilibrium

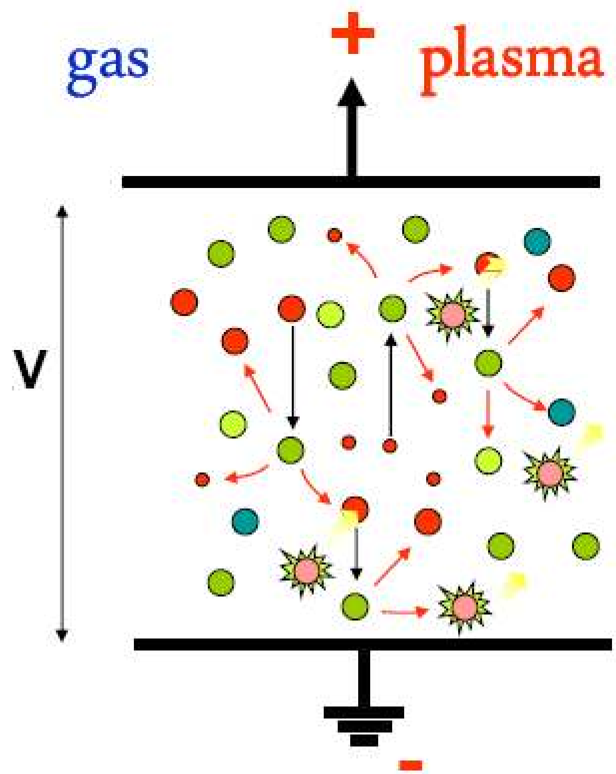
How do we make plasmas?

Supply Energy!!!
e.g. Heat transfer, radiation, electric power…

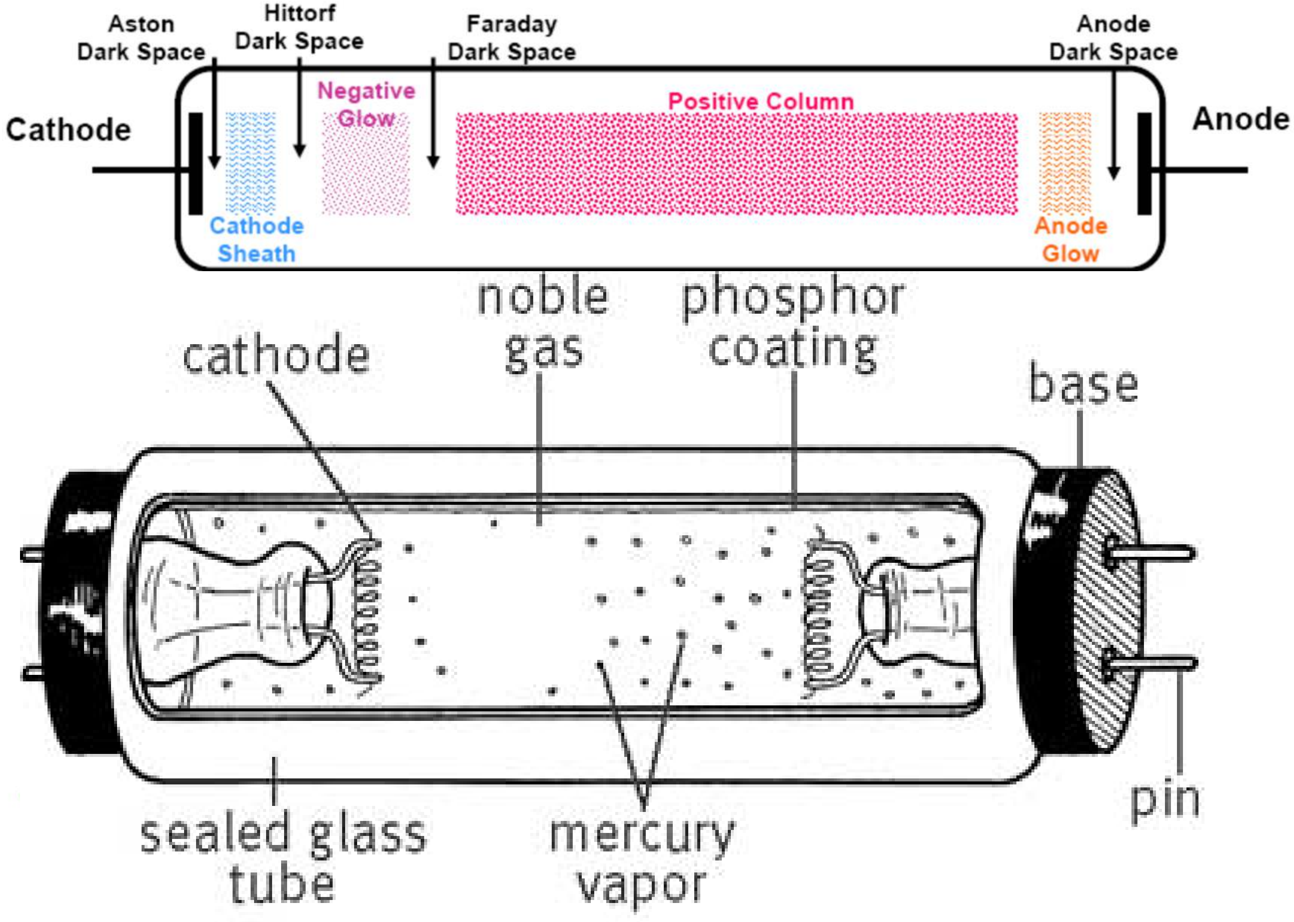
For many plasma applications, an Electric Field is applied to a gaseous environment

Plasma or Gaseous Discharge

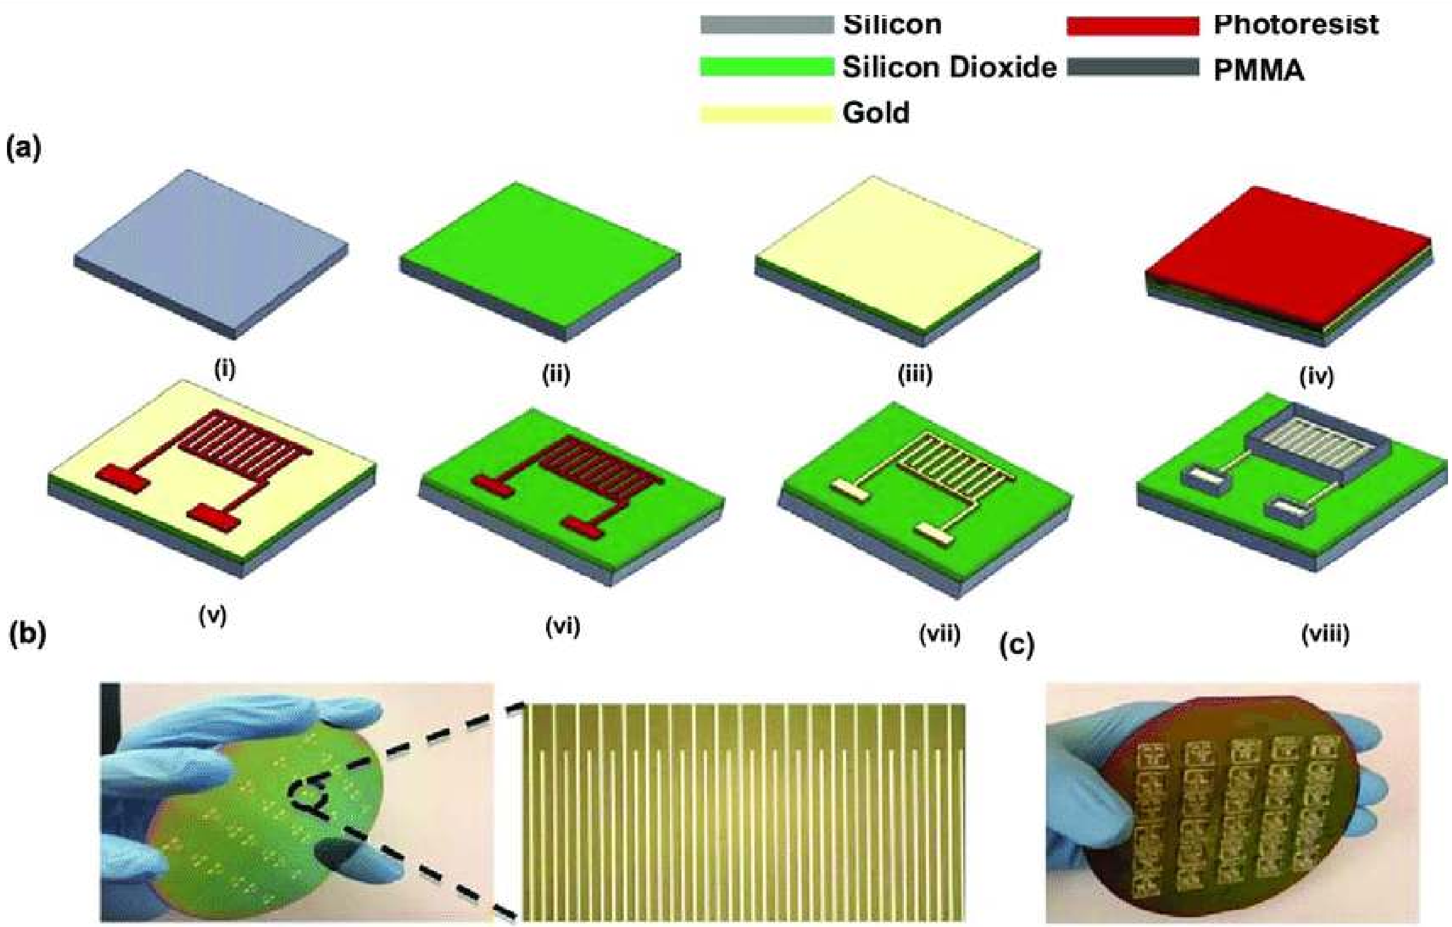
- Molecules
- Excited molecules
- Ions
- Electrons



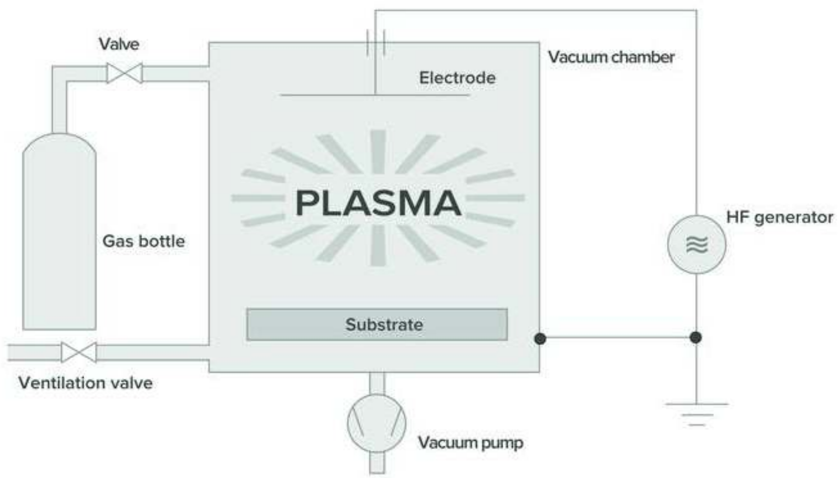
Low-Pressure Glow Discharge Plasmas



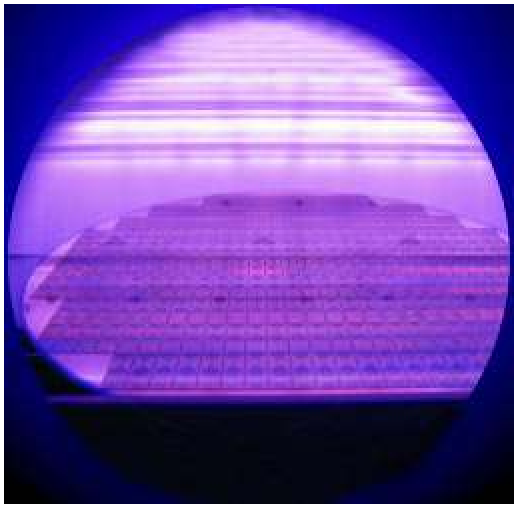
Low- Temperature Plasma enabled Microchip Fabrication

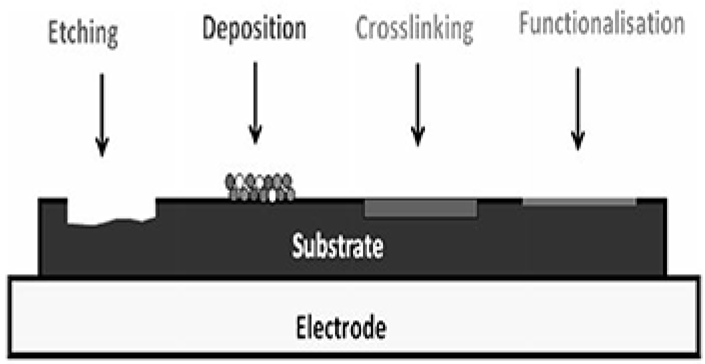


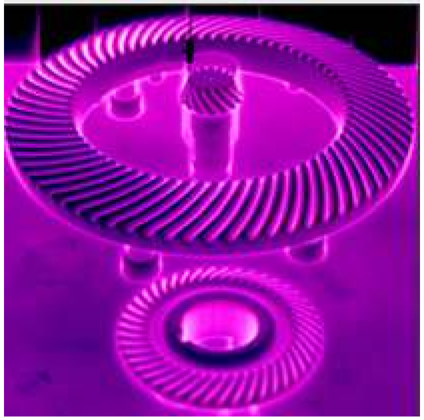
Low-Pressure, Low-Temperature Plasma Processing



Plasma processing of silicon for semiconductor manufacturing.





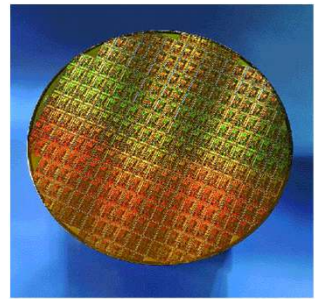


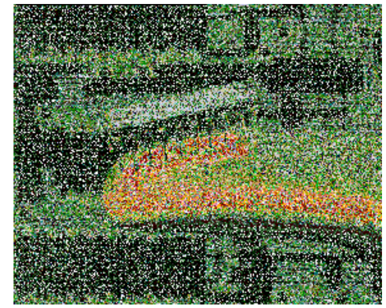
Plasma processing to harden or coat materials.

Plasmas are easier to be generated at low pressures

Low pressure plasmas
(1 mTorr ~ a few Torr)

- are well understood
- are used extensively nowadays (e.g. in semiconductor industry for computer chips manufacturing)





However, to generate low pressure plasmas:

- vacuum chambers
- expensive vacuum pumps
- pressure monitoring and pressure control devices

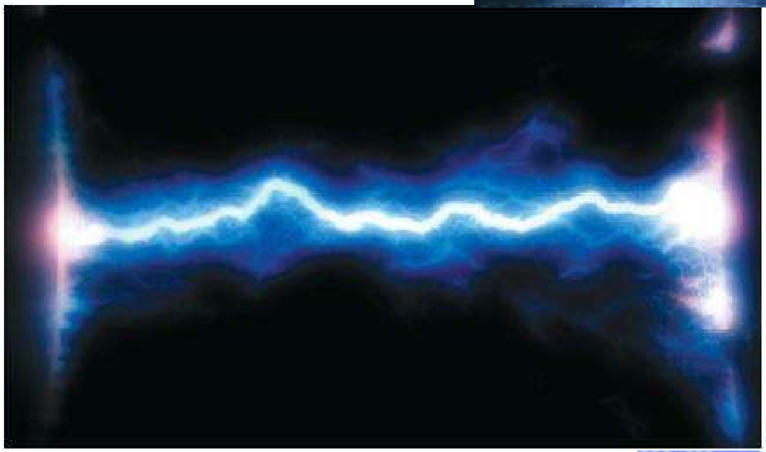
 +  +  = 

Generate Plasmas at Atmospheric Pressure!!

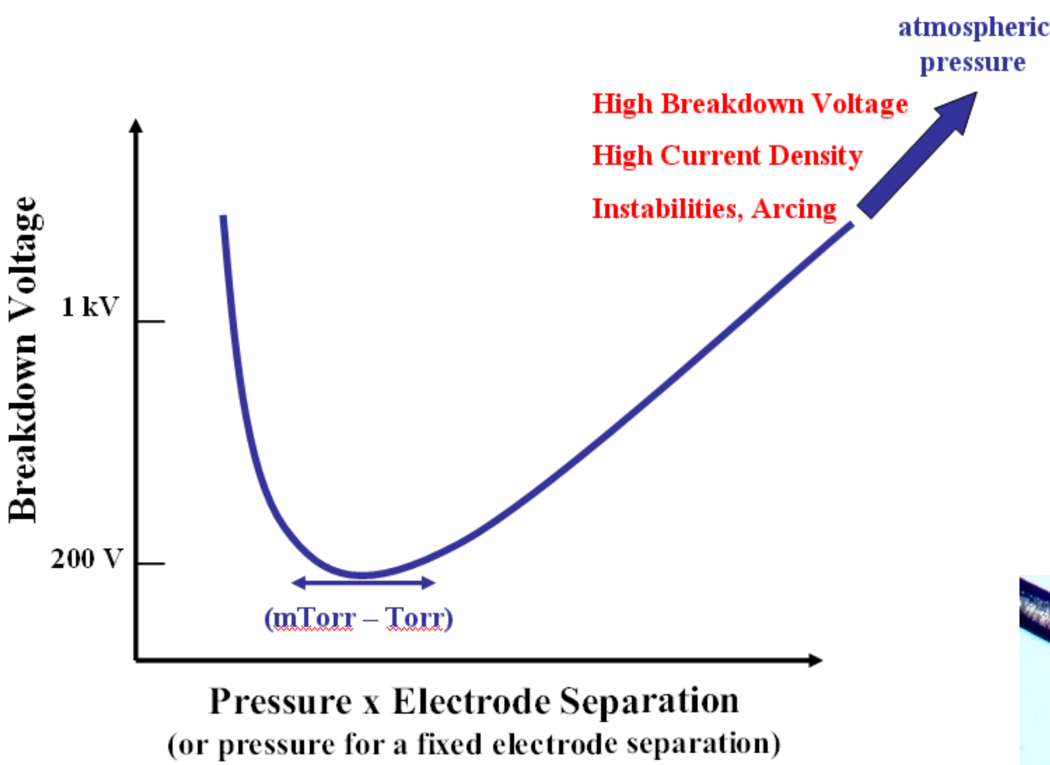
What happens at air pressure?

- No vacuum is involved
- Difficult to generate and sustain
- Run into some challenges such as glow to ***arc*** transition – Non controllable

Arc Discharge: thermal plasma
- It's hot and detrimental
- Gas temperature can reach as high as $2x10^4$ K
- Low voltage drop at cathode
- High cathode current density



High Pressure Microplasmas



Paschen Breakdown Curve

Stabilization of high-pressure plasmas: "pd scaling": "p" ↑, so "d" ↓ to keep breakdown voltage low and minimize instabilities after breakdown -

Microplasmas

Dimension: a few millimeter down to and below **100 μm**

Human Hair: 60 – 100 μm

How do we solve this problem?

Transient (pulsed) plasmas: *In atmospheric* plasmas, *for efficient gas heating at least 100-1000 colli*sions are necessary. Thus, if the plasma duration is shorter than 10^{-6} – 10^{-5} s, *gas* heating is limited. Of course, for practical purposes such plasma has to be operated in a repetitive mode, e.g., in trains of microsecond pulses with millisecond intervals.

Micro-confinement: Gas heating occurs in the plasma volume, and the energy is carried away by thermal diffusion/convection to the outside. If the plasma has a small volume and a relatively large surface, gas heating is limited.

Dielectric Barrier Discharges: These plasmas are typically created between metal plates, which are covered by a thin layer of dielectric or highly resistive material. The dielectric layer plays an important role in suppressing the current: the cathode/anode layer is charged by incoming positive ions/electrons, which reduces the electric field and hinders charge transport towards the electrode. DBD also has a large surface-to-volume ratio, which promotes diffusion losses and maintains a low gas temperature.

Advantages of Microplasmas

- Low-cost of implementation
- System flexibility
- Atmospheric pressure operation
- High densities and high reaction rates
- Fast and efficient processes
- Easy to generate and sustain for a variety of gas mixtures
- Glow-like and diffuse
- Non-equilibrium ($T_e > T_g$) *to thermal*
- Unique chemistry

… a new realm of plasma science

What can we do with it?

Material Synthesis

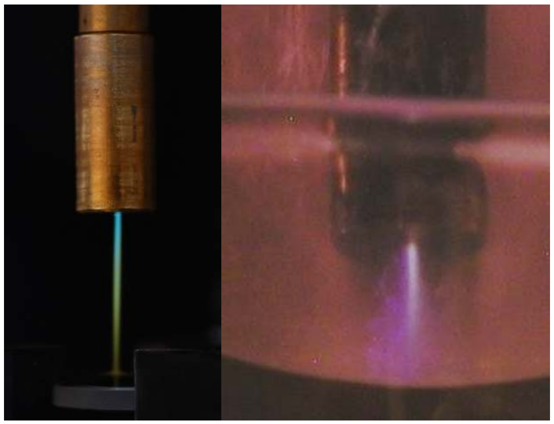
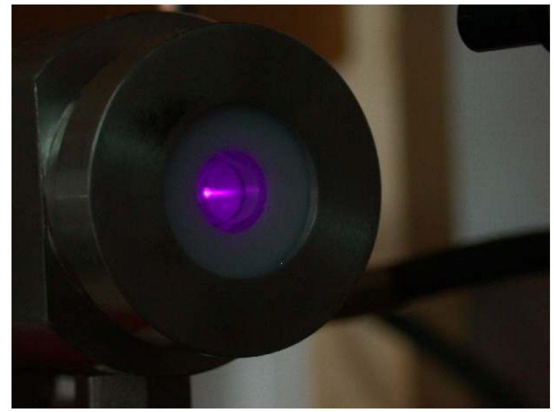
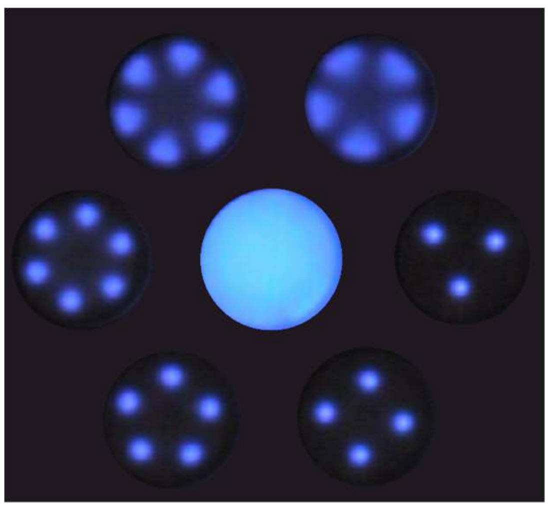
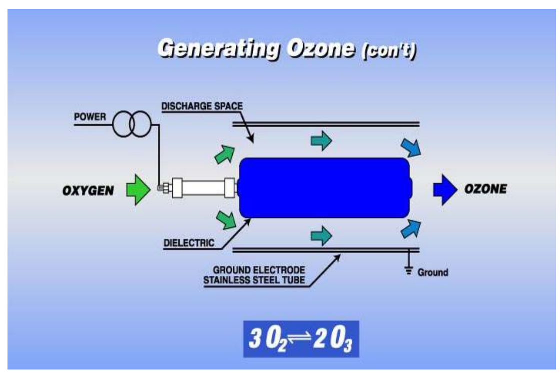
Some examples…

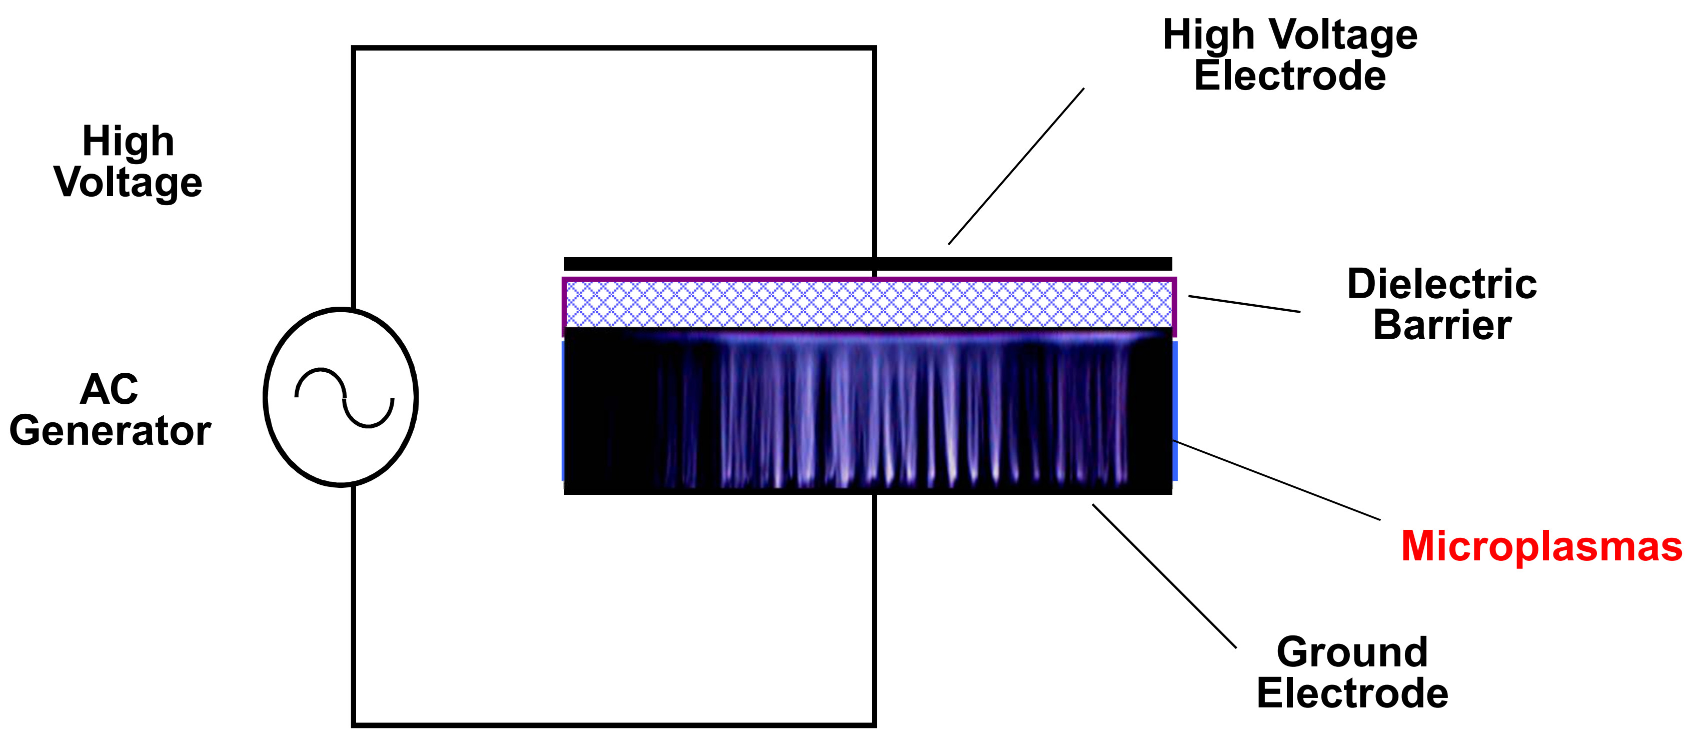








Atmospheric Pressure Cold Plasma



Role of the Dielectric (Insulator)

The dielectric is the key for the proper functioning of the discharge.

Serves two functions:

1. Limits the amount of charge transported by a single microplasma
2. Distributes the microplasmas over the entire electrode surface area

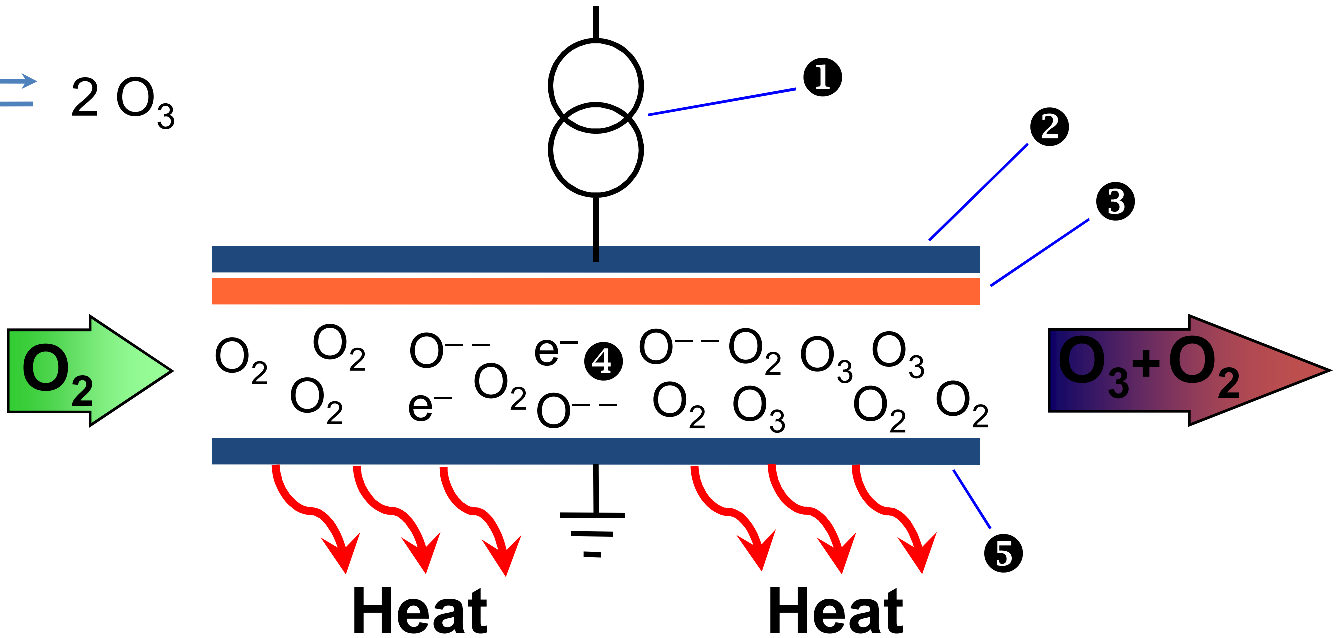
Ozone Generator

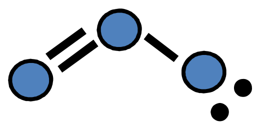
Dielectric Barrier Discharge

$$3\ O_2 \rightleftharpoons 2\ O_3$$



Properties of Ozone (O_3)

- Tri-atomic form of oxygen.



- Most powerful commercial oxidizing agent
- Unstable - must be generated and used onsite
- Limited solubility in water, but more so than oxygen
- Leaves a dissolved residual which ultimately converts back to oxygen

Major Global Challenges

National Academies of Sciences, Engineering, and Medicine have identified major global challenges in the 21st century that science and technology must help solve:

1. Energy
2. Environment
3. Water Resources
4. Agriculture and Food Security
5. Global Health / Population / Human Rights

Plasmas provide some potential solutions to many of these global challenges.
