

Langmuir probe data interpretation with a neural network

Matthew Lazo, Xin Zhang, Francesca Poli
August 12, 2020

- Electrostatic probe, bias voltage swept in time to generate current-voltage characteristic
- Useful for diagnosing plasma temperature, density and other parameters
- **Lots of data**, but Langmuir theory well-understood^{1,2}; allows training of neural network
- Theory applicable to wide range of plasmas

Example Langmuir probe trace¹

NSTX (left), STFC-1 (right)

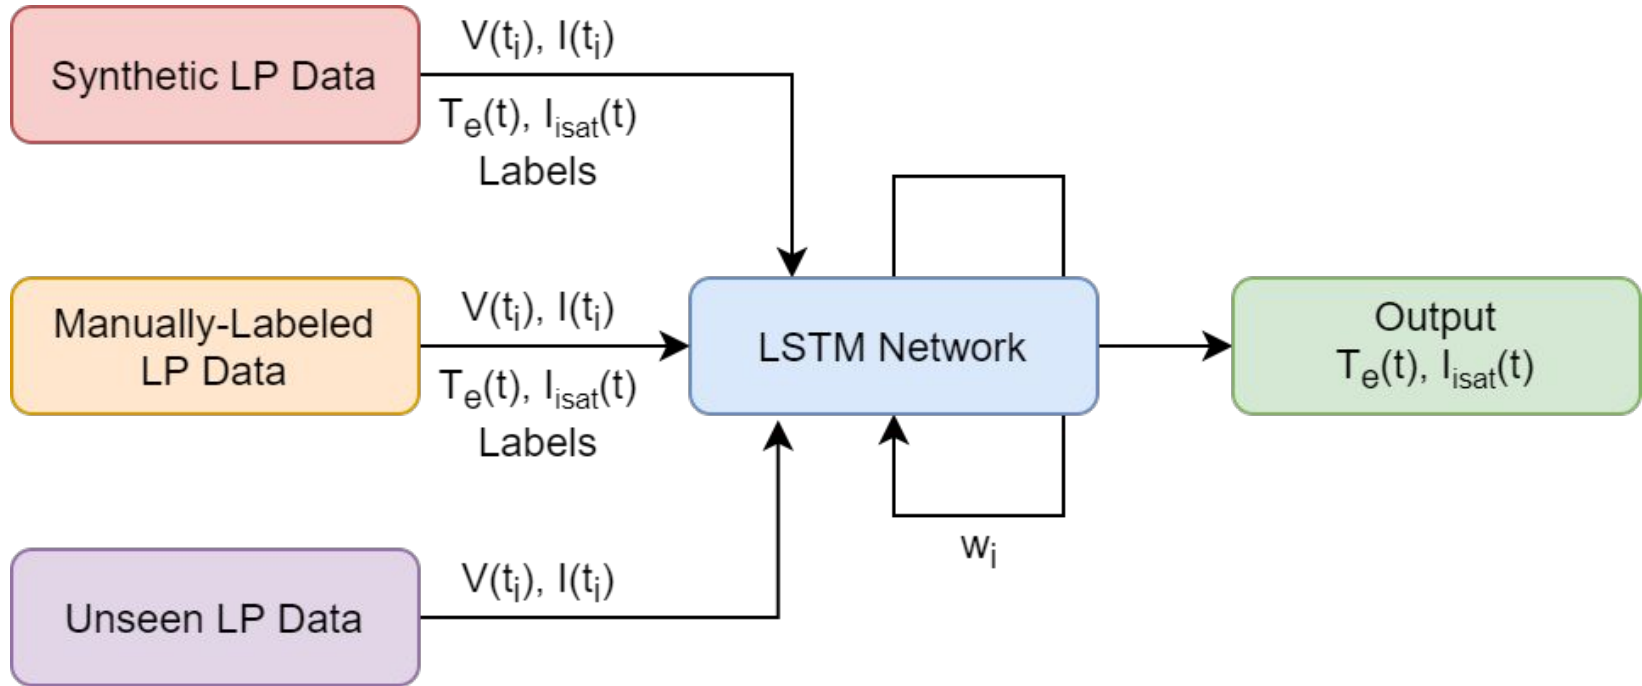

Neural Network (NN)

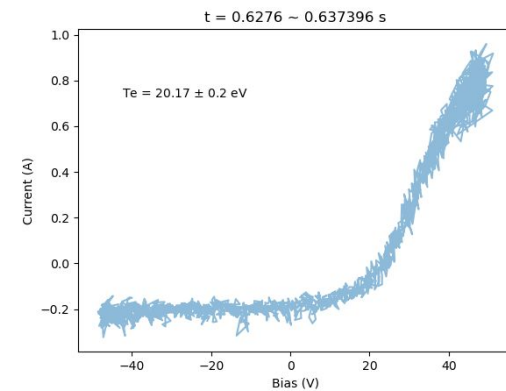

Recurrent NN (RNN)

- We use an LSTM³, one flavor of RNN, in the network
- Tensorflow by Google does a **lot** of the heavy lifting

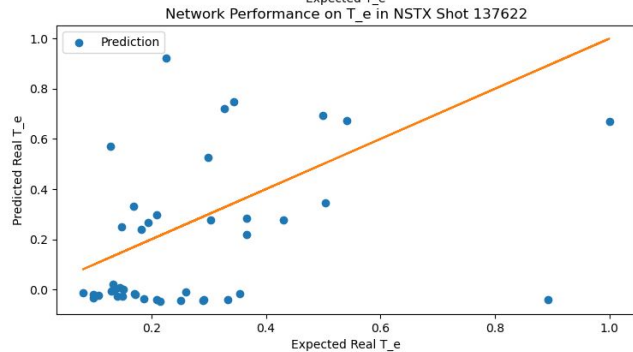

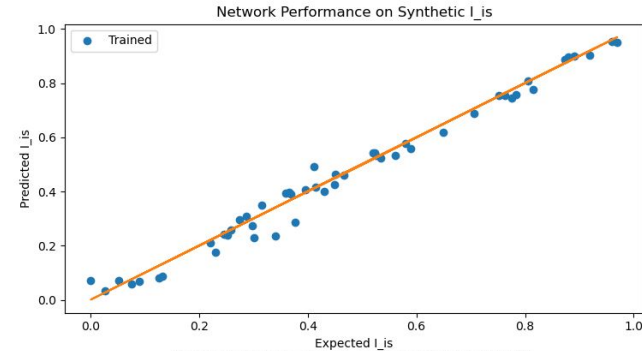

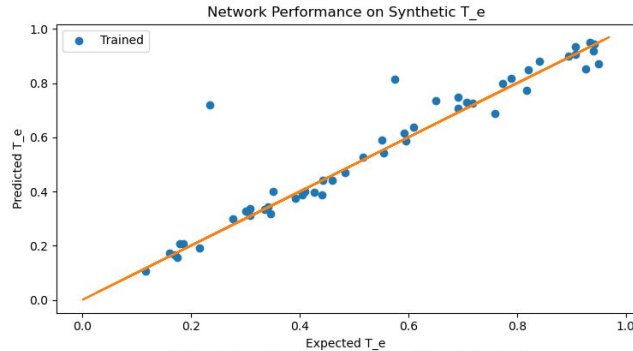

Synthetic data (top row) and NSTX data (bottom row)

- Synthetic Langmuir probe data with noise generated, network trained to label plasma parameters

- Network trained on 100,000 synthetic LP traces, validated on set of synthetic traces (top)
- Predictions made on NSTX shot 137622 (bottom)

- Predictions made on NSTX shot 137622
- Mean Squared Error loss quantifies network performance as it trains

- Improve synthetic data model
- Check and improve human analysis
- Generalize network to use with various other plasmas

This work was made possible by funding from the Department of Energy for the Summer Undergraduate Laboratory Internship (SULI) program. This work is supported by the US DOE Contract No. DE-AC02-09CH11466.

Additional thanks to Xin Zhang and Francesca Poli for helping with the completion of the project, and to Arturo Dominguez and Deedee Ortiz for being awesome program coordinators!
